

Life after prostate cancer

Insights to help you live life restored

Hope. Recovery. Support.

Every year, more than 1.1 million men are diagnosed with prostate cancer globally. It is the second most commonly diagnosed cancer in men worldwide.¹ If detected early, prostate cancer is usually curable.

Like many men, you have undergone surgical treatment for your prostate cancer. Advances in surgical techniques have allowed surgeons to successfully operate on a growing number of patients, and surgery offers the greatest chance for cure for localized prostate cancer.²

On the following pages you will find important information about what to expect after your surgery. You can refer to these tools to track your progress and learn about support resources as you move through recovery.

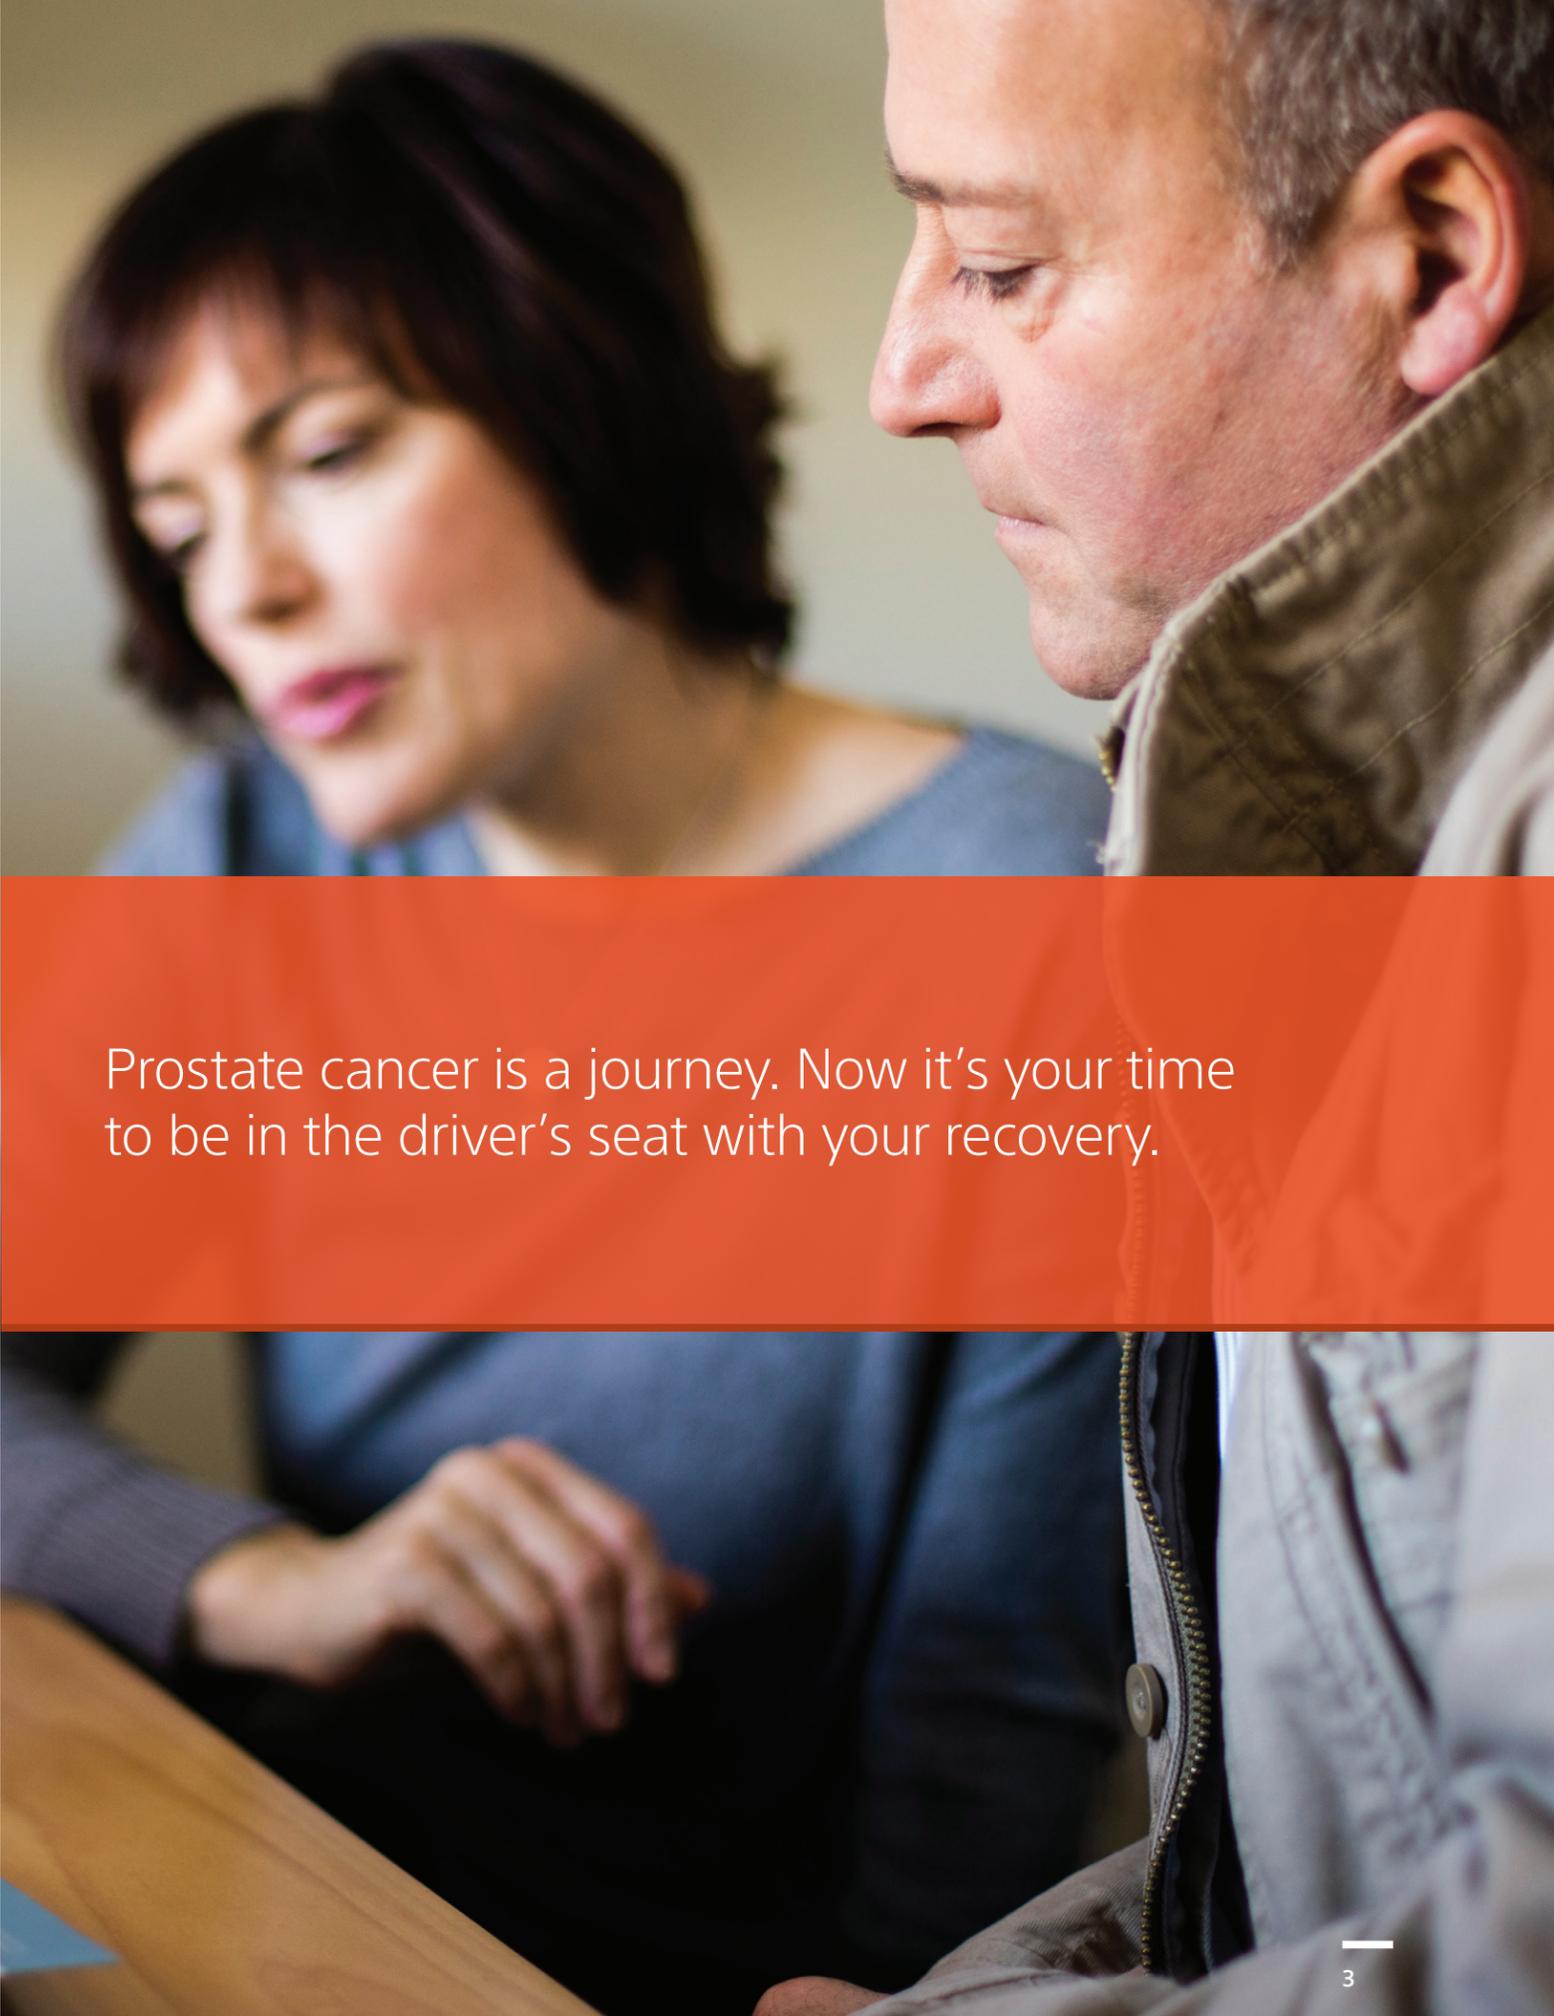

Recovering bladder control and erections

In order to remove the cancer, the nerves or muscles in your body that help control your urine flow and enable you to get an erection may have been damaged. Most men are understandably concerned about their ability to regain bladder control and erections following their prostate surgery.

While men often leak urine (experience incontinence) immediately following surgery, the leakage usually tapers off within several weeks or months.³ When incontinence persists beyond six to twelve months, you should consult your doctor.

The same is true for erectile dysfunction (ED). ED is known to be a potential complication following prostate cancer treatment. With the advent of nerve-sparing procedures, some men may regain their existing erectile function. The journey is different for every man, and some may not recover their ability to have a natural erection.

The good news is that there are multiple treatment options for incontinence and ED.

A photograph of a woman and a man sitting at a table, looking at a document together. The woman is on the left, and the man is on the right. They both appear to be focused on the document. The image is partially obscured by an orange overlay on the right side.

Prostate cancer is a journey. Now it's your time to be in the driver's seat with your recovery.

Regaining continence

Prostate cancer surgery may cause weakness in the pelvic floor muscles and the urinary sphincter that normally control urine flow. Once the catheter is removed after your surgery, you may experience symptoms ranging from light urine leakage (a few drops when you exercise, cough or sneeze) all the way to a complete inability to control your urination.

Continence tends to improve over time. While every man's situation is different, many find they are continent within six to twelve months after surgery. Recovery can be impacted by factors such as your age, your general physical health, and the degree to which you had full bladder control before the surgery. If after six to twelve months the symptoms persist, consider contacting your doctor.⁴

Understand you don't have to live with incontinence. Instead, you can choose to do something about it. You're in charge, not your incontinence.

Short-term solutions

Until urinary control returns, using absorbent pads or special absorbent underwear can help. Your doctor will also likely encourage you to perform regular pelvic floor/Kegel exercises. These isolate and strengthen the pelvic floor muscles and can help men regain bladder control following prostate surgery.⁵ It is important to do the exercises correctly and regularly. It may help to work with a nurse or physical therapist on the exercises to ensure you are doing them properly and often enough. Some men use collection devices such as external or condom catheters or urine collection pouches to avoid accidental leakage. In the weeks and months following your surgery, talk to your doctor about your treatment options and your progress in regaining continence.

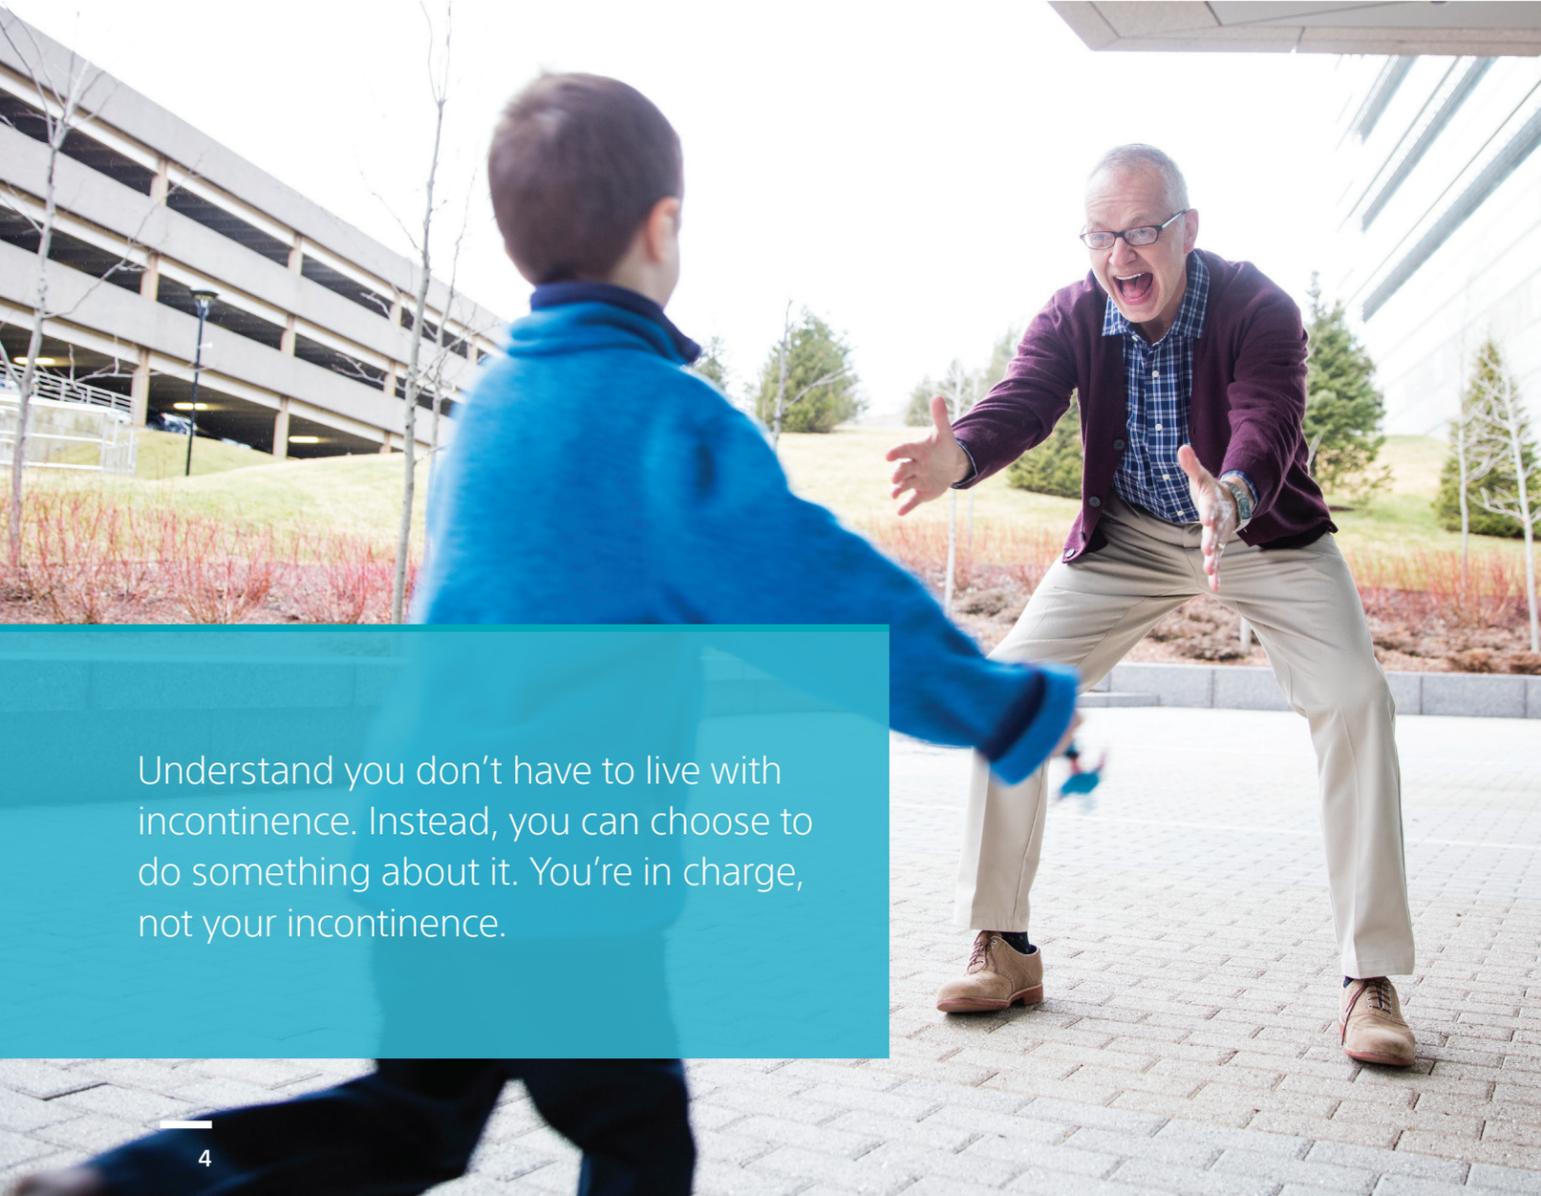

Long-term solutions

For those men who experience long-term incontinence, it's important to remember that there are effective solutions available that can restore your confidence, control and quality of life.

Injections – Injecting bulk-producing agents, such as collagen into the bladder neck, can help keep the urethra and bladder opening closed and may help prevent small leaks. Even if successful, repeated injections over time may be required to maintain continence.⁶

Male sling – The AdVance™ XP Male Sling System from Boston Scientific is positioned in the body with a minimally invasive,⁷ surgical procedure for correcting stress urinary incontinence. A small “sling” made of synthetic mesh is placed inside the body through three small incisions. The sling supports the urethra, restoring normal bladder control.⁸ Most patients are continent immediately following the procedure.⁹

Artificial urinary sphincter – The AMS 800™ Urinary Control System is the “Gold Standard Treatment” for incontinence.^{10,11} This implantable device mimics the function of a healthy urinary sphincter, closing off the urethra in order to stop the flow of urine.¹² The procedure involves implanting an inflatable cuff around the urethra, which is inflated by a fluid-filled balloon that is placed behind the pelvic bone.¹³ A pump inside the scrotum allows the man to deflate the cuff when he needs to urinate. It will automatically re-inflate, firmly closing off the urethra, preventing leakage.¹³

Restoring your sexual health

Many men find that it takes months or over a year to regain their ability to have an erection, and some men find that their ability to have an erection does not return.¹⁷ Should the ED persist, there are both short-term and long-term solutions that can be considered, and you will want to discuss which solution may be right for you.

Penile rehabilitation¹⁸

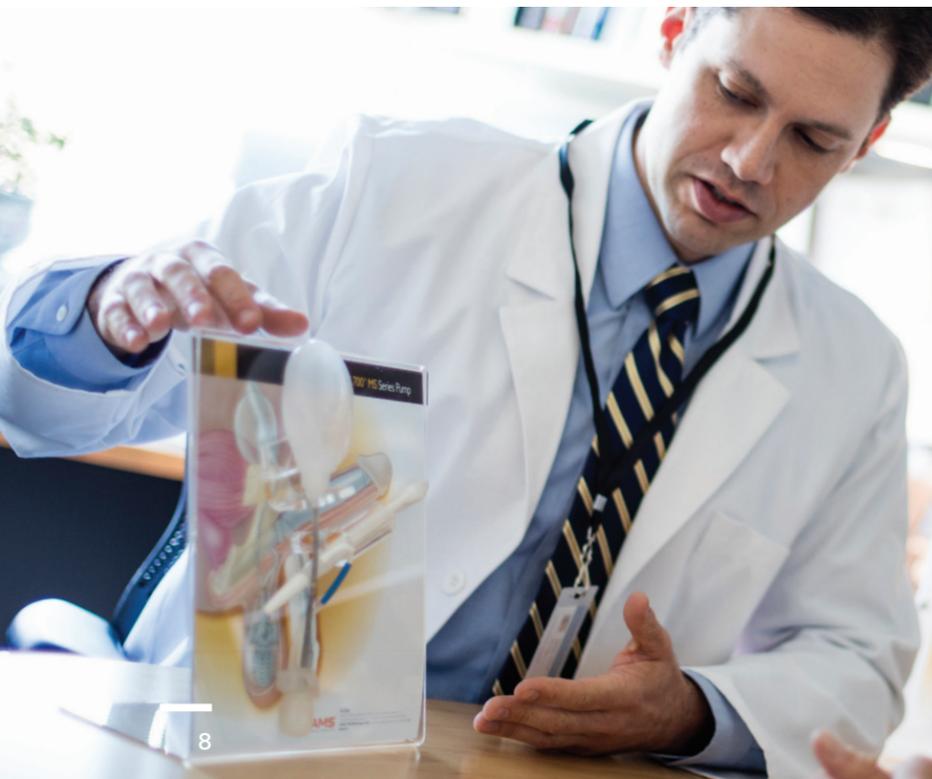

A penile rehabilitation program refers to a course of action designed to help the nerves responsible for erections recover after surgery, while maintaining the health of the penile tissue.

There are several factors that play a role in erection problems after prostate surgery. First of all, nerve damage can lead to erectile dysfunction. Even though your surgeon may have performed a “nerve sparing” operation, the techniques that are used to protect the erectile nerves may temporarily cause the nerves to be damaged and it may be more than a year before they recover.

Rehabilitation works for three reasons:

1. Gets more oxygen to the penis,
2. Keeps blood vessels healthy, and
3. Keeps muscles healthy.

Among 301 doctors from 41 countries, 84% performed or prescribed some form of penile rehabilitation. Your doctor will discuss the specifics of penile rehabilitation with you.

“The penile implant changed my life in such a way that confidence is abundant. I do not have to worry about whether or not I’m going to be able to satisfy my partner.”

Treatment options

There are multiple treatment options available for ED. For some men, oral medications don’t work,¹⁹⁻²¹ so it’s important to know all of your options. Find a solution to regain the confidence, control and wholeness you seek with an active, satisfying sex life.

Oral medications – There are a number of prescription medications (for example, Viagra,[™] Cialis[™] and Levitra[™]) available that may improve blood flow to the penis. Combined with sexual stimulation, this may produce an erection. Drug therapy is usually a first-line treatment option for most men experiencing ED, and may be used in conjunction with other methods as well.²²

Injections & urethral suppositories – With injection therapy, a small needle is used to inject medication directly into the base of the penis.²² The medication allows blood to flow into the penis, creating an erection. Many men find this method effective, but the idea of regular injections can be difficult to accept. Another option, MUSE[™] is the same drug available in the form of a small pellet (suppository) that is inserted into the opening of the penis.²²

Vacuum pumps – Pumps mechanically enhance the flow of blood into the penis. A plastic cylinder is placed over the penis, and a pump (either manual or battery operated) creates vacuum suction within the cylinder, drawing blood into the penis to create an erection. A stretchable tension band placed at the base of the penis can help maintain the erection.²²

Penile implants – When drug treatments, injections and other non-surgical therapies are not successful or unsatisfactory in resolving ED, a penile implant may be a long-term, satisfying solution. An inflatable implant uses a pump surgically placed in the scrotum to inflate and deflate the penile implant. All components are completely concealed, and the implant allows for the ability to have an erection suitable for intercourse at any time.²² Another type of penile implant is the positionable or malleable implant. It provides ease of positioning, cosmetic concealment and rigidity for sexual intercourse.²³

An erection achieved with a penile implant can be safely maintained for as long as desired, which many men and their partners find adds to the quality of their sex life.

The journey to restored sexuality

For some men – and their partners – conservative treatments (vacuum pumps, injections, etc.) for ED may not be satisfying, and may affect the quality of their sex life. Surgical solutions provide more spontaneity. Whatever you are experiencing, it’s important to maintain open lines of communication.

Involve your partner in the decision making, talk about what you are feeling, and experiment with new ways of being intimate together. The journey might be a challenging one, but working through it may actually strengthen your love life in unique ways.

Global resources

American Cancer Society is the nationwide, community-based, voluntary health organization dedicated to eliminating cancer as a major health problem by preventing cancer, saving lives and diminishing suffering from cancer, through research, education, advocacy and service.

www.cancer.org

Urology Care Foundation (UCF) formerly known as American Urological Association Foundation is the premier professional association for the advancement of urologic patient care. UCF offers a wealth of patient education and information written and reviewed by urology experts.

Frequently asked questions

How common is prostate cancer?¹

Worldwide, more than 1.1 million men are diagnosed with prostate cancer every year, making it the second most common cancer in men. Two thirds of newly diagnosed prostate cancer cases are in the developed regions of the world.

Are some men more likely to be diagnosed with prostate cancer?

Older men, African heritage, and men with a family history of the disease all have an increased likelihood of being diagnosed with the disease. The common age for all men at prostate cancer diagnosis is 66 years old.²⁶

How much does family history of prostate cancer increase my risk?

Men with a primary relative affected by prostate cancer (a brother or father) are more than two-fold as likely to develop the disease. Men with familial prostate cancer may develop the disease at an earlier age. They should begin testing with both the PSA blood test and the digital rectal examination at age 45 or even younger if they have multiple relatives with the disease.²⁷

How curable is prostate cancer?

In general, the earlier the cancer is caught, the more likely it is for the patient to remain disease-free after treatment. Because approximately 90% of all prostate cancers are detected in the local and regional stages, the survival rate for prostate cancer is very high — nearly 99% after five years.^{26,28}

What are the symptoms of prostate cancer?

If the cancer is caught at its earliest stages, most men will not experience any symptoms. Some men, however, will experience symptoms such as frequent, hesitant or burning urination, difficulty in having an erection, or pain or stiffness in the lower back, hips or upper thighs.²⁸

What are some of the side effects from removing a prostate?

The two most feared side effects of radical prostatectomy are loss of erections and urinary incontinence. These side effects can occur but there are successful treatment options available. Also, after total removal of the prostate, there is no ejaculation, although there is the sensation of climax and orgasm.²⁵

It's been a year since my prostatectomy and I still have no control of my bladder. What can I do?

Over the course of the first year following surgery, continence returns in the majority of men. However, 8%–63% of men will report some degree of SUI to be a significant problem one year after their prostatectomy.^{15,16} After 12 months, if you are still suffering from SUI, you may want to seek out a urologist who specializes in restorative procedures.

Why don't all men recover erectile function after surgery?

Post-operative erectile dysfunction is compounded in some patients by pre-existing risk factors that include: older age, cardiovascular disease, diabetes, cigarette smoking, physical inactivity and certain medications such as anti-hypertensive drugs or psychotropic medications.¹⁷

When can a man resume sexual activity after a prostate cancer surgery?¹⁷

Sexual functioning can return after surgery — usually beginning within three to six months and then having continued improvement for two to three years. Erectile dysfunction can be treated with medication, vacuum erection devices, injections or with an implant.

Will I still be fertile after a radical prostatectomy?

There should be no seminal fluid after the prostatectomy, so you will no longer be fertile. Most men will still experience orgasm.²⁵

What are penile implants?

Penile implants are a safe, surgical treatment option, have a high degree of patient satisfaction²⁹ and provide a natural feeling erection.³⁰ Ask your doctor to provide you with more information about this option.
